## **ABSTRACT**

A film surface imprinted with nanometer-sized particles to produce micro- and/or nanostructured electron and hole collecting interfaces, including: at least one substrate; at least one
photoabsorbing conjugated polymer (including polybutylthiophene (pbT)) applied on a substrate,
nanometer-sized particles including multiwalled carbon nanotubes (MWNT) to produce a charge
separation interface; at least one transparent polymerizable layer, wherein the MWNT are
embedded in the conjugated polymer to produce mixture and applied on a substrate to form a
MWNT bearing surface film layer to form a stamp surface which is imprinted into the surface of the
polymerizable film layer to produce micro- and/or nano-structured electron and hole collecting
interfaces; polymerizing the polymerizable film layer to form a conformal gap between the MWNT
stamp surface and the surface of the polymerizable film layer, and filling the gap with a
photoabsorbing material to promote the generation of photoexcited electrons and transport to the
charge separation interface.
